ABSTRACT OF THE INVENTION

FULL MULTIPROCESSOR SPECULATION MECHANISM IN A SYMMETRIC MULTIPROCESSOR (SMP) SYSTEM

Described is a data processing system and processor that provides full multiprocessor speculation by which all instructions subsequent to barrier operations in a instruction sequence are speculatively executed before the barrier operation completes on the system bus. processor comprises a load/store unit (LSU) with a barrier operation (BOP) controller that permits load instructions subsequent to syncs in an instruction sequence to be speculatively issued by the LRQ prior to the return of the sync acknowledgment. Load data returned by the speculative load request is immediately forwarded to the processor's execution units for The speculative execution with subsequent instructions. returned data and results of subsequent operations are held temporarily in the rename registers. multiprocessor speculation flag is set in the corresponding rename registers to indicate that the value is "barrier" speculative. When a barrier acknowledge is received by the BOP controller, the BOP controller messages logic affiliated with the processor's registers, which then resets the flag(s) of the corresponding rename register(s).
